A 46-year-old man had chronic granulomatous gastritis characterized by giant gastric folds with noncaseating epithelioid granulomas including giant cells in the corpus. No definite etiologic factors were detected. Histology and the rapid urease test indicated that *H. pylori* was present in both the antrum and corpus. The granulomatous gastritis with giant gastric folds improved after *H. pylori* eradication. This case suggests an association between isolated granulomatous gastritis and *H. pylori* infection. (Gut and Liver 2009;3:137-140)

Key Words: Granulomatous gastritis; *Helicobacter pylori*; Hypertrophic gastritis

INTRODUCTION

Chronic granulomatous gastritis (CGG) is a rare disease.1,2 It constitutes about 0.3% of all cases of gastritis and is characterized by the presence of granulomas.2,3 Idiopathic granulomatous gastritis (IGG) refers to a chronic granulomatous reaction limited to the stomach without the identification of specific underlying causes,4 therefore its pathogenesis and the optimal treatment is controversial. Currently, *Helicobacter pylori* (*H. pylori*) infection is considered a cause of chronic granulomatous gastritis and the associated giant gastric folds.5,7 Here, we report a case of CGG that improved after *H. pylori* eradication.

CASE REPORT

A 46-year-old man was transferred to the department of Internal Medicine with the suspicion of gastric cancer. By the routine Upper gastrointestinal series, an ill-defined mass like lesion in the gastric corpus was detected. There was no specific past history and the patient did not complain of any significant symptoms. Physical examination and laboratory findings were within normal limits. The upper endoscopy showed an ill-defined 4×3 cm area with regional hypertrophied gastric folds at the great curvature from the lower to the mid body of the stomach (Fig. 1A). The mass had a soft consistency noted with the endoscope. The upper gastrointestinal series and abdominal CT showed mucosal fold thickening at the great curvature and lower body of the stomach (Fig. 2). The gastric biopsy tissue obtained showed several granulomas in five biopsy fragments. The diameter of the granulomas was variable. The smallest measured less than 0.10 mm in diameter. The range of sizes was 0.10-0.40 mm. The granulomas were localized either superficially, i.e., just underneath the surface epithelium, or deeply, down to the level of the foveolar isthmi. They consisted of a diffuse cellular infiltrate, a circumscribed aggregate or a compact ‘sarcoid-like’ aggregate (Fig. 3A). The results of the PCR study for *Mycobacterium tuberculosis* were negative. Other study (colonoscopy, small bowel series) shows no abnormal finding. However, *H. pylori* testing were positive both in the antrum and in the corpus by histology and rapid urease test (Fig. 3B). The patient was treated with triple therapy (rabeprazole 20 mg + amoxicillin 1,500 mg + clarithromycin 600 mg for 1 week) for *H. pylori* eradication. Follow-up upper endoscopy, after two months, showed decreased gastric fold thickening and the gastric atrophy was improved. However, the biopsy specimens showed focal granulomas without *H. pylori* detected. The endoscopy findings and granulomas all improved one year...
Fig. 1. (A) Upper gastrointestinal endoscopy showing focal enlarged gastric rugae with hyperemic changes at the greater curvature side of the lower body of the stomach. (B) Upper gastrointestinal endoscopy showing that the giant fold improved after *H. pylori* eradication.

Fig. 2. (A) Double-contrast barium study showing focal thickened and irregular folds at the greater curvature side of the lower body of the stomach. (B) Abdomen tomography showing thickened folds at the greater curvature side of the lower body.

DISCUSSION

Chronic granulomatous gastritis (CGG) is uncommon. It may occur in association with several disorders including Crohn’s disease, sarcoidosis, infectious diseases, foreign body reaction, malignancy and vasculitis. In the West, the common causes of chronic granulomatous gastritis are Crohn’s disease and sarcoidosis, but in the East, the incidence of *H. pylori* infection has been reported to be high with CGG without the presence of systemic illness. Our case was negative for immunohistochemical staining (CD20, CD21, CD35) and had no other underlying disorder (Crohn’s disease) for upper gastrointestinal series and colonoscopy.

The association between CGG and *H. pylori* was first reported in 1989. A high percentage of *H. pylori* organism was identified in all-chronic granulomatous gastritis cases whatever the diagnosis was. *H. pylori* was detected in 90% and chronic gastritis with atrophy was present in 95% of biopsy specimens. Miyamoto et al. reported two cases of IGG that completely resolved after *H. pylori* eradication.

The pathogenesis of granuloma formation with *H. pylori*...
