Folliculitis decalvans is a chronic purulent folliculitis resulting in follicular atrophy and permanent hair loss. Due to unclear etiology, it is difficult to treat folliculitis decalvans. A wide variety of topical and systemic agents have been tried previously, with variable results. We report 27-year-old male presenting with relapsing pruritic, pustular outbreaks on the scalp, which led to areas of permanent baldness. Before visiting our hospital, he was misdiagnosed as tinea capitis, and had taken itraconazole 200 mg a day for 6 months, but with no clinical improvement. In our hospital, histopathologic exam confirmed the diagnosis of folliculitis decalvans, microbial culture and Periodic acid-Schiff stains for fungi were negative. Intralesional injections were performed with triamcinolone acetonide at a concentration of 5 mg/mL every two weeks. Oral isotretinoin was prescribed concurrently 10 mg twice daily. After 16 weeks, inflammatory lesions on the scalp were markedly decreased, and at the same time clinical symptoms such as itching or pain were much improved. We think that the combination of intralesional steroid injection and oral retinoid may be an effective therapy for the conservative management of folliculitis decalvans.

Digital mucous cyst is a benign ganglion cyst of the digits, typically located at the distal interphalangeal joints or in the proximal nail fold. It usually occurs on the hands, although it has also been noted on the toes. It is characterized by a round to oval, translucent, smooth nodule containing a clear gelatinous fluid that may discharge spontaneously or on minor trauma. The etiology of the cyst is uncertain but may involve mucoid degeneration. It usually presents as a solitary lesion, and multiple lesions are uncommon. We report a case of multiple digital mucous cysts which developed on the both 5th fingers.
